Brain Development, Social Context and Justice Policy
Elizabeth Scott^{*}, Natasha Duell^{}, and Laurence Steinberg^{***}**

Justice policy reform in the past decade has been driven by powerful research evidence indicating that brain development is ongoing through adolescence, and that neurological and psychological immaturity likely contributes in important ways to teenagers' involvement in crime. Courts (including the Supreme Court¹), legislatures and agencies increasingly view juvenile offenders as different from their adult counterparts, and accept that the legal response to juvenile crime should attend to these differences. An emerging consensus holds that the criminal law goals of fairness, accountability and crime prevention are advanced by policies that deal less punitively with most juveniles than with adults and that sanction juveniles in developmentally appropriate ways.²

Although lawmakers and the public increasingly accept the argument for developmentally-based justice policies, some skepticism remains. A typical response by those unpersuaded that developmental science has powerful legal and policy relevance is to point out that many (perhaps most) adolescents do not engage in serious criminal activity; thus, normative biological and psychological factors associated with adolescence are unlikely to play the important role in juvenile offending that is posited by those supporting the reform trend.³ Not surprisingly, these skeptics are inclined to discount the relevance of adolescent immaturity to justice policy.⁴

⁴ Critics, such as Justice Scalia have noted that advocates view adolescents as mature for purposes of making abortion decisions. See *Roper*, 543 U.S. at 617 (Scalia, J., dissenting).

To be sure, not all adolescents commit crimes - and, certainly, very few commit serious offenses.⁵ As the skeptics' challenge suggests, the argument for developmentally-based justice policies is oversimplified if it is taken to mean that features associated with biological and psychological immaturity alone lead teenagers to engage in illegal conduct. The decision to offend, like much behavior in adolescence, is the product of dynamic interaction between the still-maturing individual and her social context. In this essay, we analyze this intricate relationship and clarify how social environment influences adolescent choices in ways that incline or deter involvement in crime and in other risky behavior.

The claim that social context influences teenage criminal behavior is familiar,⁶ and relatively uncontroversial. What has not received much attention is the relationship between biology (and psychology) and environment, and the mechanisms through which particular tendencies and traits associated with adolescent brain development interact with environmental influences to encourage antisocial or prosocial behavior. Brain development in adolescence is associated with reward-seeking behavior and limited future orientation.⁷ It is also associated with increased sensitivity to external stimuli, and particularly with heightened susceptibility to peer influence, which in turn contributes to emotional arousal and impulsivity⁸. In short, social environment can play a powerful role in inclining teenagers toward risk-taking (and generally in shaping adolescent behavior), because, compared to adults, adolescents are particularly responsive to external stimuli (particularly peers), easily aroused emotionally, and less able to regulate strong emotions. Because they are easily aroused, adolescents are also more sensitive to threats than are adults.⁹ These external influences can override the adolescent's still developing ability to make reasoned decisions.

These tendencies associated with adolescent brain development may be manifested in different teenagers in different ways; heightened tendencies toward risk-taking may impel

antisocial acts in some teens, but more aggressive play on the athletic field in others.¹⁰

Depending on the nature of the social environment, these biologically-driven inclinations can be activated “in the moment” to contribute to risky behavior, including fast driving, excessive drinking, unsafe sex and criminal activity. In this article, we examine the interaction between developmental tendencies and contextual influences that promote or deter risk-taking and criminal involvement.

The endogenous factors that contribute to risky behavior are normative in adolescence; although studies find substantial variations in individual propensities, adolescents, on average, exhibit these tendencies and engage in risk-taking to a greater extent than do adults. Indeed, the combination of reward-seeking, impulsivity, easily aroused emotions, and susceptibility to peer influence leads a large percentage of teens to occasionally behave in ways that could be the basis of criminal charges.¹¹ But a teenager who lives in a high-crime neighborhood with many antisocial peers is more likely to get involved in criminal activity than one in a neighborhood with few such peers, even though the two may not differ in their tendencies and propensities for risk-taking.¹² Developmental tendencies might lead the first youth to engage in criminal activity, something he would likely not consider on his own. If instead, his peers were into car racing, or if drugs were readily available and popular in the neighborhood, risk-taking behavior might take these forms. And if he were a member of a close-knit and highly competitive basketball team, the interaction of peer influence and reward-seeking might lead to the sort of risk-taking on the basketball court that is socially accepted.

Scientific knowledge about the interaction between the developing adolescent and his or her social context is also important in designing correctional facilities and structuring programs for juveniles. For juveniles in the justice system, the correctional facility or program constitutes the social environment for development during the period of the sanction, and the correctional setting can have either a positive or negative impact on the young offender’s future life. The adolescent brain is more malleable, or “plastic,” than that of adults,¹³ and because of increased

plasticity, teenagers are particularly responsive to environmental stimuli, both positive and negative; during this formative developmental stage,¹⁴ those environmental influences can shape the trajectory of individuals' lives. Psychologists explain that healthy maturation during adolescence is an extended and interactive process between the individual and her social context, in which opportunities in the social environment facilitate or impede accomplishment of developmental tasks necessary to effective adult functioning.¹⁵ A justice policy that aims to reduce recidivism and maximize the potential for juvenile offenders' transition to non-criminal adulthood recognizes the importance of social context by structuring programs and facilities to promote positive development during this formative stage.

Our inquiry into the dynamic interaction between brain development in adolescence and social context offers powerful support for policies that subject adolescent offenders to more lenient sanctions than adults receive and that tailor dispositions to juveniles' developmental needs. Our examination confirms and illuminates the Supreme Court's conclusion that juveniles deserve less punishment than adult offenders because their offenses are driven by biological and psychological immaturity, and also because, as legal minors, juveniles cannot extricate themselves from social contexts (neighborhoods, schools and families) that contribute to involvement in crime.¹⁶ Our interactive model also confirms that correctional facilities and programs are social settings that can support healthy development to adulthood in individual offenders, but can also affect young offenders' lives in harmful ways. Thus our analysis provides a sound empirical and theoretical foundation for developmentally-based justice policies that have emerged over the past decade. Our analysis also informs a long-standing debate of whether an offender's deprived social environment mitigates criminal responsibility. Proponents argue that mitigation applies to defendants who have experienced severe deprivation on the ground that their impoverished environment undermined their ability to act as law abiding citizens.¹⁷ This

¹⁷ See David Bazelon, *The Morality of the Criminal Law*, 49 S. CAL. L. REV. 385 (1976). Judge Bazelon first developed the argument in *Alexander v. United States*, 471 F. 2d. 923, 957-65 (D.C. Cir. 1973). The argument was developed more fully by Richard Delgado, "Rotten Social Background': Should the Criminal Law Recognize a Defense of Severe Environmental Deprivation?," 3 LAW & INEQ. J. 9 (1985). See also Richard Delgado, *The Wretched of the Earth*, 2 Ala. Civ. Rts & Civ. Lib. L. Rev 1 (2011); Andrew Taslitz, *The Rule of Criminal Law:*

argument has been largely dismissed as undermining free will and as diluting responsibility for a broad range of offenders.¹⁸ Our analysis narrows and sharpens the claim that social context is relevant to the punishment of juveniles on both retributivist and consequentialist grounds.

A brief roadmap of the article may be helpful. In Part I, we review the research evidence describing biological and psychological features of adolescent brain development that are relevant to risk-taking and offending. This research offers powerful support for the legal judgment that juveniles' criminal choices often are influenced by factors associated with normative development. Part I concludes with a description of recent cross-cultural research indicating that these attributes inhere in adolescence as a developmental stage and are not solely the product of particular social contexts.¹⁹

Part II analyzes how the traits described in Part I can influence behavior in a variety of ways depending on social context, resulting in neutral, anti-social, or prosocial outcomes. As we explain, environmental factors can minimize or intensify the extent to which emotional factors contribute to risk-taking behavior—and the kinds of risky behavior chosen. Most important is the influence of peer group (constituted of other reward-seeking and impulsive adolescents). Part II then focuses directly on criminal involvement; the interaction between social context and normative biological and psychological factors in the still maturing individual can influence the teen's involvement in an antisocial peer group and in criminal activity. And in most teens, this interaction abates as the adolescent matures, leading to desistance. Part II describes briefly a category of young offenders less likely than normative adolescents to desist from antisocial activity with maturity because their offending is driven by various dispositional and environmental factors, many of which predated adolescence, and not primarily by the interaction of developmental factors and social context.

Part III explains how the social environment provided by the justice system's sanctions can impede or enhance healthy brain development, because the facilities and programs through which law responds to juvenile crime create the social context for the developing young offender. Evidence of brain malleability supports that social context can influence development in a positive or negative direction, and other research points to elements of that context that can facilitate healthy maturation.

Part IV analyzes the implications for law and policy of the interactive model of juvenile offending. The analysis provides powerful support constitutional and legal trends that have emerged in the past decade based on the premise that juveniles are different from adult offenders and that the justice system should recognize these differences. Our analysis confirms conventional wisdom that immature brain development influences offending, but also explains how the teen's interaction with his or her social context plays an important role. We also clarify how correctional programs can facilitate or undermine healthy development in adolescence, and highlight the importance of social context as a key element in policies that aim to prevent crime and promote desistance in young offenders.

I. Psychological and Biological Immaturity

In this Part, we describe the features of psychological and neurobiological development in adolescence that form the foundation of our interactional model of teenage risk-taking behavior. This growing body of developmental research provides powerful support for the constitutional principle that "children are different,"²⁰ and for the growing trend toward acknowledging these differences in the legal response to juvenile crime. The research also clarifies that the developmental tendencies that contribute to involvement in crime also incline adolescents toward risk-taking generally, and that offending is a part of a larger picture.

Adolescent risk-taking can be understood, in part, as arising from a "maturity gap" between cognitive and psychosocial development. It is well understood that emotional and social maturation lags behind intellectual development and that adolescents' capacity for self-regulation is immature. As compared to adults, adolescents are particularly inclined toward reward-seeking and are extremely sensitive to their social context and particularly to peers. This combination of

²⁰ See *Miller v Alabama* 567 U.S. ____ (2012);

features contribute to emotional arousal.²¹ And when teenagers are emotionally aroused, they tend to make impulsive, short-sighted choices and engage in risky behavior that they might understand are ill-advised when considered in a neutral setting. This Part then describes a “dual systems” model of brain development offered by developmentalists to explain this tendency toward impulsive risky choices: While brain systems implicated in reward seeking and sensitivity to peers develop early in adolescence around puberty, brain systems that govern self-regulation mature gradually through adolescence and into early adulthood.²² Finally, this Part explains that these attributes and tendencies are endogenous to the developmental stage of adolescence and are found in teenagers across cultures.

A. Developmental Factors Contributing to Risk-Taking.

This section describes three features of adolescence that likely contribute to adolescents’ inclination to engage in risky behavior to a greater extent than adults. Both biological and behavioral research confirms that, as compared to adults, adolescents are more inclined toward reward-seeking, more sensitive to social context, and more impulsive in their choices, especially under conditions of emotional arousal. Each of these tendencies is linked to normative brain development.

1. Reward Seeking.

Substantial research evidence supports that adolescents are sensitive to rewards and inclined toward reward- or sensation seeking to a greater extent than adults, and that they focus on rewards rather than risks in making choices. As discussed below, this inclination is normative in adolescence; indeed, increased sensation seeking is adaptive developmentally as it encourages adolescents to explore their environment and to develop a sense of identity and autonomy.²³ But reward-seeking interacts with teenagers’ sensitivity to peers in ways that can contribute to harmful risk-taking.

During early adolescence, regions of the brain associated with “incentive processing,” or the valuation and prediction of rewards, undergo substantial changes resulting in heightened reward

Ellis et al., *The Evolutionary Basis of Adolescent Behavior: Implications for Science, Policy, and Practice* 48 DEV. PSYCH. 598, 598-623 (2012).

sensitivity during this period.²⁴ These changes have been linked to hormonal developments during puberty that increase the number of dopamine receptors in the brain that are implicated in approach behaviors and the experience of pleasure.²⁵ As a result, adolescents evince increased dopamine cell firing in response to rewarding stimuli,²⁶ which affects feedback learning, sensitivity to social evaluation and loss, and incentive-driven responses.²⁷

Neurodevelopmental studies of risk behavior generally suggest that heightened risk taking in adolescence is associated with greater activation of reward-sensitive brain regions among adolescents as compared to adults.²⁸ In brain imaging studies, when presented with images of rewarding stimuli, such as smiling faces, adolescents evince a stronger response in reward-processing regions than do children or adults. Moreover, the extent to which individuals show this sensitivity to reward is correlated with risk taking.²⁹ This suggests that risk taking is, to some extent, intrinsically rewarding to adolescents, or that adolescents are more sensitive to the potential rewards associated with risks.

A large body of behavioral research confirms that adolescents are more sensitive to rewards and more inclined toward reward-seeking than are adults; these findings are consistent with the neurobiological evidence. In these studies, reward seeking is typically measured using self-report scales that assess characteristics such as thrill- or novelty- seeking, or behavioral tasks that assess responsiveness to rewarding stimuli (such as monetary rewards). For example, some studies use gambling tasks in which individuals must learn to discriminate between gambles that are likely to be rewarding (e.g., drawing cards from a deck that is likely to pay off) and those that are likely to be costly (e.g., drawing cards from decks that are likely to lead to losses).³⁰ Others have used “temporal discounting” tasks, in which players are asked to choose between smaller,

immediate rewards (e.g., \$200 today) versus larger, but delayed ones (e.g., \$1,000 in six months).³¹

Both self-report³² and behavioral³³ studies of reward seeking indicate that this behavior peaks in mid-adolescence, and subsequently declines in adulthood. Cross-sectional studies of performance on gambling tasks demonstrate that mid- to late adolescents learn from rewards at a faster rate than do their younger peers or adults, and that the tendency to learn more quickly from rewarding experiences than from costly ones is substantially stronger among teens than among adults, who tend to learn from rewarding and costly experiences at similar rates.³⁴ Studies of temporal discounting have found that younger adolescents demonstrate a stronger preference for smaller, immediate rewards, whereas older adolescents and adults are willing to wait longer for larger ones. Young adolescents also have been shown to characterize themselves in self-report surveys as being less future oriented (i.e., regulating behavior in favor of long-term goals) and less inclined to consider future consequences of one's actions.³⁵ Thus, middle adolescents (ages 15 through 17) demonstrate a heightened sensitivity to rewards compared to younger or older individuals, and this sensitivity seems to motivate decision-making that is oriented toward the present rather than the future, even if the future-oriented decision is superior.

2. Sensitivity to Social Environment.

Adolescence is a period of heightened sensitivity to the social environment and the individual's relationship to that context. Recent research indicates that a network of brain systems governing thinking about social relationships undergoes significant changes in adolescence in ways that increase individuals' concern about the opinion of other people, particularly peers.³⁶ These brain regions, sometimes collectively referred to as "the social brain," are more easily activated in adolescence than before or after, making teenagers especially attuned

to both positive and negative emotions of those around them.³⁷ During this developmental period, individuals are more sensitive to both praise and rejection than are either children or adults, making them potentially more susceptible to peer influence, and responsive to threat.³⁸

Recent evidence sheds light on the relationship between peer sensitivity and reward seeking in adolescence, with important implications for adolescent risk taking. Jason Chein and colleagues have examined the impact of the presence of peers on individuals' neural responses to a potential reward, comparing adolescents between ages 14 to 18, with younger (19 to 22) and older (24 to 29) adults making decisions in a simulated driving task. The study found that observation by peers increased activation in reward-related brain regions in adolescents, but not in the adults, and that activity in these regions predicted risk-taking (running a stoplight to complete the task faster) in the tasks.³⁹

Much behavioral research confirms adolescents' sensitivity to peers, and finds a correlation between peer influence and risk-taking in adolescence. Social scientists have studied age differences in responses to peer influence by presenting individuals with hypothetical dilemmas involving peer influence. Studies presenting participants with situations involving pressure to engage in antisocial conduct have found that peer influence increases between childhood and mid-adolescence and declines slowly during the late adolescent years.⁴⁰ Peer influence can operate directly when teenagers' respond to peer pressure; but desire for peer approval and fear of rejection also affect adolescents' choices more than those of adults.⁴¹ The increased salience of peers likely makes their approval especially important in group situations; it is not surprising, perhaps, that juveniles are far more likely to offend in groups than are adults.⁴²

⁴² See Franklin E. Zimring & Hannah Laqueur, *Kids, Groups, and Crime: In Defense of Conventional Wisdom* 52 J. RES. CRIME DELINQ. 403, 403-413 (2015).

It is well established that adolescents take more risks in the presence of peers than when they are alone or with an adult,⁴³ and that this “peer effect” is not found among adults.⁴⁴ The presence of peers also influences risk preference among adolescents; adolescents (but not adults) are more likely to endorse the benefits of risky activities relative to costs in the presence of peers than when they are alone.⁴⁵ One study has found that the presence of peers increases risk-taking among adolescents even when they are given information about the probability of positive and negative outcomes.⁴⁶

3 *Impulsivity and Cognitive Control*

When adolescents are emotionally aroused by the anticipation of rewards in the presence of peers, they tend to make riskier choices that they are less able to control than do adults. As described in Section B below, deficits in self-control in adolescence are thought to derive from immaturity in the system of cognitive regulation centered in the prefrontal cortex and its connections to social and emotional brain regions. This system develops slowly during adolescence and is not fully mature until the early to mid- twenties. In adolescence, it can be overwhelmed by emotional and social responses, contributing to short-sighted choices.⁴⁷

Studies measure self-regulation using both self-report scales that assess the tendency to act without thinking (e.g., “I act on the spur of the moment”) and behavioral tasks that require individuals to resist making automatic, reactive responses to specific stimuli. Studies of self-reported impulse control find that this psychological trait improves into early adulthood.⁴⁸ Age patterns in studies involving behavioral tasks are more complex. On simple tasks requiring only that participants inhibit an automatic response, individuals demonstrate adult levels of self-

regulation by mid-adolescence.⁴⁹ In contrast, mature performance is not observed until early adulthood when tasks involve distractions that cause attentional interference or that require planning and complex reasoning.⁵⁰

The most interesting recent research measuring impulse control has compared responses to behavioral tasks under neutral (non-emotional) and emotional conditions. These studies have found that adolescents perform more poorly on self-control tasks under emotional conditions and that performance under both conditions under both neutral and emotional conditions improves into adulthood.⁵¹ A major study sponsored by the MacArthur Foundation Research Network on Law and Neuroscience (of which two of us were members) is illustrative. In this research, almost 150 adolescents, (between 13 and 17), young adults (18 to 21) and older adults (age 22 to 25) were asked to perform a standard task measuring self control under neutral conditions and conditions involving positive and negative emotional arousal (anticipation of winning money versus hearing an aversive sound). Under conditions of positive arousal, adolescents' performance on the self-control task was substantially poorer than that of the two adult groups, while under conditions of negative arousal, both the adolescent and young adult group performed more poorly than the older adults. Moreover, under emotionally arousing conditions, young adults evinced decreased activation in cognitive control networks and increased activation in brain regions implicated in emotional processing; this combination is thought to have contributed to poorer performance on the self-control task.⁵² Another recent study found that those adolescents whose self-control was disrupted during emotionally arousing tasks engaged in more risk-taking during driving simulation tasks than did same-aged individuals whose self-control

⁴⁹ For example, on the Stroop task, participants are asked to quickly and accurately indicate the color in which a word is displayed while ignoring its semantic meaning. When a color word is displayed in an incongruent color (e.g., the word 'blue' displayed in green font), the participants must inhibit the automatic response to read the word and instead respond on the basis of the word's physical color. Studies using the traditional Stroop color-word task find no differences in cognitive control between mid-adolescents and adults. See Jessica R. ⁵¹ For example, studies using an emotional version of the Stroop (see Id.) in which colors and color-words are replaced with emotional faces and phrases, report improvements in self-regulation into adulthood. Even under neutral conditions, adolescents perform more poorly than older adults. See Cohen, *supra* note 6 on 2.

⁵² See Alexandra O. Cohen et al., *The Impact of Emotional States on Cognitive Control Circuitry and Function* 28 J. COG. NEUROSCI. 446, 446-59 (2016).

was less disrupted.⁵³ Other studies have shown that social arousal, created by the presence of peers, activates reward regions in the adolescent brain,⁵⁴ which in turn is associated with riskier decision making.⁵⁵ The evidence that emotional contexts interfere with self-control in adolescence sheds light on teenagers' heightened tendency to engage in risk taking in emotionally and socially arousing contexts.⁵⁶

* * *

Together with research demonstrating that adolescents tend to evince greater reward seeking and relatively less self-regulation compared to adults, studies also show that these psychological traits are linked with greater engagement in risk taking. For example, higher levels of reward seeking have been associated with self-reported substance use, delinquent acts, and risky driving, as well as risk taking on several laboratory measures of risk taking. Similarly, greater impulsivity has been associated with higher rates of self-reported substance use and delinquent activity, as well as with increased risk taking on behavioral risk taking tasks.⁵⁷

B. Dual Systems Model of Risk Taking.

Developmental scientists in recent years have offered “dual systems” or “maturational imbalance” models in seeking to explicate the relationship between emotional immaturity and risk-taking. Brain maturation comprises several processes that vary in their developmental timetable across different brain regions: Dual systems models emphasize research showing that brain systems involved in reward seeking and those regulating self-control follow different developmental trajectories.⁵⁸ This imbalance, it is believed, results in poor regulation of

emotions and a tendency to focus on the immediate rewards of choices, while discounting long-term costs; this combination increases inclinations to engage in risky behavior, including offending.⁵⁹

Neurodevelopmental research indicates that the development of subcortical brain regions implicated in socioemotional processing is more or less completed by adolescence. As explained above, these developments stimulate reward seeking and increase sensitivity to peers, beginning with the onset of puberty and diminishing as individuals mature into young adulthood, such that these responses are particularly powerful during adolescence. But the prefrontal cortex and other brain regions involved in impulse control and emotional regulation develop slowly through adolescence and are not mature until early adulthood.⁶⁰ The prefrontal cortex plays a key role in advanced cognitive abilities, including planning ahead, comparing risk and reward, and self-regulation. Immaturity in the prefrontal cortex is thought to make adolescents more susceptible to impetuous decisionmaking and more vulnerable to the effects of emotional and social arousal on cognitive functioning than are mature adults.⁶¹

Maturation of the prefrontal cortex involves multiple processes that are ongoing during adolescence but completed at different ages.⁶² For example, synaptic pruning, which increases the efficiency of information processing, is largely complete by mid-adolescence; thus basic cognitive capacities of reasoning and understanding are adultlike by about age 15 and improve little in later years. In contrast, connectivity between prefrontal regions and the regions that process rewards and respond to emotional and social stimuli social are not fully established until individuals are in their mid-twenties.⁶³ These connections are critically important to emotional regulation and impulse control. The prefrontal regions are implicated in feedback evaluation, integrating experiential information to guide future behavior, and controlling emotional impulses

in favor of long-term goals.⁶⁴ The lack of functional connectivity leaves adolescents more prone than adults to making emotion-based decisions with inadequate cognitive oversight and suggests why aspects of social and emotional functioning are slower to mature than basic cognitive functioning. Adolescents' deficient capacity to regulate behavior in the face of highly arousing stimuli may lead to suboptimal decisionmaking in contexts requiring the coordination of emotion and thinking. In sum, brain systems that govern "cold cognition" (thinking under neutral conditions) reaches adult levels of maturity long before those that govern "hot cognition" (thinking under conditions of social and emotional arousal).⁶⁵

c. Cross-cultural Research on Brain Development.

For the most part, the developmental brain research that has informed our understanding of various aspects of the dual systems model has been conducted in the United States and a few Western European countries (most notably, the Netherlands).⁶⁶ Because expectations and norms for adolescent behavior vary considerably around the world, it is important to ask whether the account of the sensation-seeking, impulsive teenager that emerges from these studies accurately represents young people in other cultural and economic contexts. Adolescence in America and much of Western Europe is a time during which a certain degree of recklessness, especially in its socially acceptable forms, is tolerated—and perhaps even encouraged. Does this characterization of adolescents apply to young people growing up in less individualistic (and perhaps less permissive) cultural contexts?

A recent extensive study of more than 5,000 people between the ages of 10 and 30 from 11 different countries suggests that it does. Laurence Steinberg and colleagues used identical test batteries to measure likely contributors to adolescent risk taking in a diverse sample of countries (China, Colombia, Cyprus, India, Italy, Jordan, Kenya, the Philippines, Sweden, Thailand, and the United States) to determine whether the trajectories of sensation seeking,

⁶⁴ See Antoine Bechara, *Decision Making, Impulse Control and Loss of Willpower to Resist Drugs: A Neurocognitive Perspective* 8 NAT. NEUROSCI 1458, 1458-63 (2005).

⁶⁶ This includes research on heightened reward sensitivity during adolescence, protracted maturation of cognitive control through adolescence and into young adulthood, and the resulting propensity of adolescents, relative to children or adults, to engage in risk taking. See Laurence Steinberg et al., *supra* note 11 on 4.

self-control, and risk-taking are similar in these varied cultural contexts. Importantly, some of these countries are relatively more tolerant of adolescent recklessness (e.g., Sweden, and the United States), whereas in others, young people are expected to demonstrate strong self-control (e.g., China and Jordan). Although there were differences among countries in patterns of psychological functioning, there were important and striking similarities.

Three such similarities are especially relevant to the present discussion:

First, age trajectories of sensation-seeking and self-control that have been described in studies of American youth were observed internationally.⁶⁷ Scores on a composite measure of sensation-seeking (combining both self-reports and behavioral indicators) followed an inverted U-shaped pattern, increasing between preadolescence and late adolescence, peaking during the late teen years, and declining thereafter. On average, the peak was observed at a slightly older age (19 years) than had been reported in previous studies of American youth. Perhaps this is due to somewhat later onset of puberty, which has been shown to contribute to the increase in reward sensitivity in adolescence,⁶⁸ in less developed nations than in developed ones; this would shift the average peak in sensation seeking to an older age when the sample is aggregated. In contrast, self-control matured gradually between preadolescence and the mid-20s, at which point it plateaued in some countries (e.g., China, Italy) but continued to mature further in others (e.g., Colombia, Cyprus); generally speaking, the prolonged maturation of self-control into the late-20s was more likely to be seen in countries in which the increase during adolescence was less dramatic. Taken together, these results suggest that the characterization of the late teen years as a time during which reward seeking is heightened and self-regulation is still maturing applies cross-culturally.

Second, the researchers found in other countries the inverted-U shaped trajectory of risk-taking that has been observed in the United States, with risky behavior more common during adolescence than before or after.⁶⁹ This set of analyses distinguished between real-world risk taking, measured through self-reports of involvement in activities such as drinking, riding with an intoxicated driver, vandalism, and fighting, and risk taking propensity, assessed with

⁶⁷ See Laurence Steinberg et al., *supra* note 11 on 4.

⁶⁹ See Natasha Duell et al., *Age Patterns in Risk Taking Across the World*, *J. YOUTH ADOL.* (in press).

experimental tasks such as a the video driving game described earlier. The authors hypothesized that age patterns in real-world risk taking would be more culturally variable than age patterns in risk taking propensity, since the former is both a function of developmental immaturity and contextual opportunity, whereas the latter is not influenced by contextual conditions (i.e., the test setting was identical across the various countries). This hypothesis was confirmed: Countries were significantly more similar with respect to trajectories of risk taking propensity than with respect to real world risk taking. Further, as expected, risk taking propensity peaked earlier than did real-world risk taking, suggesting that the manifestation of adolescents' inherent inclination to engage in risky behavior is delayed by the real world context in which development occurs. Finally, the peak age for antisocial risk taking was earlier (around age 19, similar to that reported in studies of the "age-crime curve") than that for health risk taking (which peaked in the mid-20s), presumably because the latter can be delayed by societally imposed constraints that are age-related (for example, age restrictions on purchasing alcohol). This study is especially relevant to our interest in this essay, because it shows how the maturationally-driven tendencies inherent in adolescence can be tempered by social context.

Third, the researchers observed in the international sample the "maturity gap" found in American studies (described above),⁷⁰ in which cognitive abilities such as working memory reach adult levels of maturity well before the psychosocial capacities thought to contribute to reckless behavior in adolescence.⁷¹ Age patterns in cognitive abilities were far more similar internationally than patterns in psychosocial capacities; this likely is due to relatively greater cultural variability in expectations for psychosocial maturity than for intellectual competence. Most importantly, whereas the main period for maturation of cognitive competence was during early adolescence (tending to plateau around age 16), in virtually all of the countries studied considerable psychosocial maturation took place during the late teens and early 20s.

*

⁷⁰ See Laurence Steinberg et al., *supra* note 57 on 14.

⁷¹ See Grace Icenogle, et al., *Adolescents' Cognitive Capacity Reaches Adult Levels Prior to Their Psychosocial Maturity: Evidence for a "Maturity Gap" in a Multinational Sample* (under review).

This Part has explained that psychosocial factors associated with adolescent brain development contribute to a tendency toward risk-taking that declines as individuals mature. These tendencies are normative in adolescence and found across cultures. In the next Part, we turn to the questions of how these inclinations interact with social context and why teenagers vary substantially in the extent and form of risk-taking.

II. Social Environment and Risky Behavior in Adolescence

Risk-taking in adolescence is driven by developmental factors, but as this Part explains, the individual adolescent's social context plays a critical role in triggering risky behavior; it also influences the forms of risk-taking in which the teenager engages. As the description of behavioral and biological research in Part I explained, endogenous developmental traits and tendencies associated with adolescence contribute to a heightened sensitivity to the social environment and an inclination to respond intensely to exciting and threatening stimuli in that environment; these stimuli contribute to emotional arousal, which in the face of immature self-regulatory competence, can overwhelm the adolescent's cognitive capacity for rational choice, contributing to reckless behavior. This dynamic interaction is especially likely to be triggered in the presence or with the encouragement of peers, since adolescents are particularly oriented toward peers and susceptible to peer influence.⁷² Peers play an important role in determining the extent and form of risk-taking in which an individual adolescent engages. Thus, an important contextual variable contributing to whether an adolescent becomes involved in criminal behavior is the degree to which his or her peer group is antisocial.⁷³ This Part explores how developmental changes in emotional arousability and self-regulation interact with the adolescent's social context to shape his or her peer affiliations in ways that can lead to involvement in risky activities; it also suggests why and how these tendencies dissipate and risk-taking declines with maturation.

A. Decision-making in a Neutral Context

As the discussion in Part I confirms, by mid-adolescence, individuals have the cognitive capacity to make rational decisions that is similar to that of adults. A teenager can understand and process information, engage in hypothetical thinking to compare alternative options and

⁷² See discussion _ to _ infra.

⁷³ Gary Sweeten, Alex Piquero, & Laurence Steinberg, *Age and the Explanation of Crime, Revisited*, 42 J. YOUTH & ADOLESCENCE 921 (2013).

make reasoned decisions.⁷⁴ In short, when not subject to exogenous influences that undermine rationality, the normative adolescent usually is a competent decision-maker. This has been confirmed, for instance, in studies of competence to stand trial, which does not improve after age 15.⁷⁵

Much research supports the conclusion that adolescent decision-making is comparable to adults under neutral conditions, but deteriorates when disrupted by external stimuli that contribute to emotional arousal. Early studies finding that adolescents were adult-like in their decisionmaking were conducted in laboratory settings under conditions in which the teenage subjects were undistracted by external influences and had time to respond to vignettes without stress.⁷⁶ Two important bodies of research focused on comprehension of Miranda rights and ability to give informed consent to medical treatment. These studies found that that by mid – adolescence, teenagers performed similarly to adults.

More recent research has sought to compare the impact on adolescent decision-making of neutral settings and settings in which subjects are exposed to external stimuli associated with emotional arousal. To test decision-making under states of emotional arousal, researchers have designed laboratory tasks with reward components (e.g., presenting images of happy faces or offering a monetary reward) and threat components (e.g., exposing participants to the possibility of hearing an aversive noise). Findings from these studies suggest that adolescents act more impulsively in the presence of both rewarding and threatening stimuli than under more neutral conditions.⁷⁷ Impulsive decision-making in the presence of an emotional stimulus has been associated with decreased activity in brain regions implicated in behavioral control and increased activity in brain regions involved in emotional processing. Research evidence also suggests that, compared to adults, adolescents take more risks in the presence of rewarding stimuli.⁷⁸ In contrast, adolescents show comparably better impulse control and engage in less risky decision-

BEHAV. 129 (1992) (study of abortion).

⁷⁷ See Cohen et al., supra note 9; B.J. Casey et al., *Braking and Accelerating of the Adolescent Brain*, 21 J. RES. ON ADOLESCENCE 21 (2011).

⁷⁸ Figner et al., supra note 47.

making in neutral contexts (e.g., in the absence of a reward or peers). Thus, research examining the impact of emotional stimuli on adolescent decision-making generally suggests that teenagers demonstrate a neural sensitivity to both rewards and threats that undermines impulse control and increases risky decision-making.

The interaction of social context with the decision-making competence of older adolescents is important in some legal settings. For example, a mature minor is likely competent to make a medical decision, which typically is made in a relatively neutral context. The adolescent is not likely to be subject to external conditions that contribute to emotional arousal or impulsive decision-making. Peers are seldom present and the inclination toward sensation-seeking is unlikely to be stimulated by the anticipated short-term rewards of treatment, which are likely to be gradual.⁷⁹ Given these conditions, it is not surprising perhaps that mature minors are authorized to consent to some medical treatments without involving their parents, because they are presumed competent to do so.⁸⁰ In contrast, although laboratory studies have found that adolescents comprehend the meaning of *Miranda* rights,⁸¹ there is good reason to question whether a juvenile in the real world setting of an interrogation room is likely to make a competent decision about waiving or asserting these rights. The stress of interrogation is compounded by police tactics that combine implicit threats of punishment unless the juvenile agrees to waiver and promises of rewards (such as permission to end the interrogation). Substantial evidence indicates that juveniles waive their *Miranda* rights at a much higher rate than do adults, and confess falsely at a higher rate.⁸² It seems likely that the competence that

⁷⁹ Steinberg et al, 2009, supra note __. Cosmetic treatment is excluded under the mature minor rule, in part because health benefits are minimal. RESTATEMENT, CHILDREN AND THE LAW (COUNCIL DRAFT) §19.01, Medical Decisions by Mature Minors (2017). Adolescents might also be more inclined to make impulsive decisions to obtain cosmetic treatment, focusing on immediate rewards.

⁸⁰ See, e.g., *Cardwell v. Bechtol* 724 S.W.2d 739, 748 (Tenn. 1987) (adopting the mature minor doctrine, factoring in “age, ability, experience, education, training, and degree of maturity or judgment obtained by the minor, as well as upon the conduct and demeanor of the minor at the time of the incident involved..., totality of the circumstances, the nature of the treatment and its risks or probable consequences, and the minor’s ability to appreciate the risks and consequences.”). Mature minors are authorized to make abortion decisions without involving their parents. *Bellotti v. Baird*, 443 U.S. 622 (1979). Although this decision may be associated with more stress than other medical decisions, the adolescent has the opportunity to deliberate, distinguishing it from “in-the-moment” choices associated with risk-taking.

⁸¹ Thomas Grisso, *Juveniles’ Capacities to Waive Miranda Rights: An empirical analysis*, 68 CAL. L. REV. 1134 (1980).

⁸² Saul M. Kassin, *The psychology of confessions*, 4 ANN. R. L. & SOC. SCI. 193 (2008).

teenagers show in the research setting is compromised by emotional factors in this social context, justifying special scrutiny of juveniles' waivers and confessions.⁸³

A final example provides a transition to our discussion of adolescent risk taking in the next section. In laboratory studies, adolescents are capable of perceiving the risks associated with different behaviors as well as adults, and are no worse than adults at estimating their vulnerability to risk.⁸⁴ In fact, some studies suggest that adolescents overestimate the risks associated with various behaviors, including getting sick from alcohol or contracting a sexually transmitted infection.⁸⁵ But in the presence of peers and free of adult supervision, teenagers' cognitive awareness of risk may do little to deter participation in dangerous, but exciting, activities such as drinking, drug use, fast driving and criminal offending. The confluence of (exogenous) opportunities for participation, and the adolescent's inclinations toward reward-seeking can lead to reckless choices driven by emotional arousal. Through similar mechanisms, the perception of threat in the social context can lead to emotional arousal, undermining rationality and contributing to impulsive decisions.⁸⁶

⁸³ RESTATEMENT, CHILDREN AND THE LAW (COUNCIL DRAFT), Rights of a Juvenile in Custody §14.21 (2016) (describing cases finding that juveniles are particularly vulnerable to coercion and that special scrutiny of waivers is required). Another important dimension of decisionmaking is background knowledge. Adults often rely on intuitive, non-deliberative decision-making, but they are more likely to make a less risky choice because they have knowledge and experience to lead them to that choice. Adolescents may lack this useful background. In the case of waiving their *Miranda* rights, not only do they have to make a choice on-the-spot in a stressful situation, but many youths also have limited or no knowledge of the implications of their choice. Bonnie L. Halpern-Felsher et al., *The role of behavioral experience in judging risks*, 20 HEALTH PSYCHOL. 120 (2001); Elizabeth P. Shulman & Elizabeth Cauffman, *Deciding in the Dark: Age Differences in Intuitive Risk Judgment*, 50 DEV. PSYCHOL. 167 (2014).

⁸⁴ Valerie F. Reyna & Frank Farley, *Risk and Rationality in Adolescent Decision Making: Implications for Theory, Practice, and Public Policy*, 7 PSYCHOL. SCI. IN THE PUB. INT. 1 (2006).

⁸⁵ Susan G. Millstein & Bonnie L. Halpern-Felsher, *Judgments about Risk and Perceived Invulnerability in Adolescents and Young Adults*, 12 J. RES. ON ADOLESCENCE 399 (2002). In one study exploring age differences in risk perception, individuals between the ages of 11 and 24 were asked to evaluate the riskiness, dangerousness, potential harmfulness, and relative costs of each of a series of risky activities such as riding in a car with a drunk driver, having unprotected sex, or shoplifting. Young adolescents ages 11-13 years were more likely than any other age group to rate these activities as risky, scary, dangerous, and more harmful than beneficial. After age 13, there were no age differences in risk perception; adolescents' risk perceptions were no different than those of younger teens Elizabeth Cauffman et al., *Age Differences in Psychosocial Capacities Underlying Competence to Stand Trial* (2002) (presented at the Society for Research on Adolescence biennial meeting).

⁸⁶ Cohen et al, *supra* note 9; Erika E. Forbes et al., *Neural Systems of Threat Processing in Adolescents: Role of Pubertal Maturation and Relation to Measures of Negative Affect*, 36 DEV. NEUROPSYCHOLOGY 429-452; [also see](#) Kassir, *supra* note 82.

B. Risk-taking in Adolescence: The Risk-Inclined Individual in Risky Social Context.

As the preceding section suggests, in a neutral setting, a normative adolescent is a competent decision-maker who perceives the risks of dangerous choices as accurately as adults. In this section, we explore why many adolescents (and young adults) engage in risk-taking behavior at higher rates than older adults. We posit that much risk-taking behavior is a product of an adolescent inclined toward exciting or rewarding experiences (the normative adolescent), whose social context presents opportunities facilitating the pursuit of those experiences and whose peers encourage engagement in risk behaviors or enhance the salience of the potential rewards associated with risk taking. “Opportunity” has two components: First, the risky activity must be accessible in the teenager’s social context; and second, the adolescent associates with willing peers who encourage participation.⁸⁷

1. *Parental Influence and Accessibility of Risky Activity.*

Adolescents are free to engage in risky behavior to a greater extent than younger children in part because they are subject to less supervision by parents and other adult authority figures. Developmentally appropriate separation from parents and increased freedom to associate with peers without supervision is a necessary part of normal maturation and healthy development, a process through which teenagers learn to make their own decisions without external control.⁸⁸ But less monitoring by parents who (presumably) mature impulse control and an interest in promoting their children’s welfare leaves teenagers with less protection against developmentally normative impulsive choices and behavior.

Some parents, of course, exercise more supervision over their teenage children than others. The role that parents assume during this developmental stage can affect whether adolescents are allowed to pursue risky activities without constraint or are subject to appropriate discipline (which, to some extent, can limit opportunities for risk-taking).⁸⁹ The challenge for parents is to find the right balance between rigid restriction of their children’s freedom and lax disengagement. Developmentalists explain that authoritative parenting is critically important to

⁸⁷ Adolescents sometimes engage in risky activities without peers, as we discuss below, of course; frequently they may anticipate peer approval.

⁸⁸ STEINBERG, *AGE OF OPPORTUNITY* at 44 (2014); Ellis et al., *supra* note 23.

⁸⁹ Ralph J. DiClemente et al., *Parental Monitoring: Association With Adolescents' Risk Behaviors*, 107 *PEDIATRICS* 1363 (2001).

healthy development in adolescence.⁹⁰ Authoritative parenting involves active engagement with the teenager's life, but not excessive monitoring, which can either generate intense opposition or inhibit development of the ability to make autonomous choices and live independently. The upshot is that even the best parenting will not prevent adolescent risk-taking. Optimally, parents (and other adults in authority) will present adolescents with opportunities to take developmentally appropriate risks, such as playing on a sports team, and seek to minimize opportunities for engaging in risks that compromise adolescents' health and well-being.

The freedom that adolescents need to separate from parents and learn to be independent, combined with the normative traits and tendencies of this developmental stage, increases teenagers' vulnerability to involvement in risky activities. The extent to which teenagers engage in risk-taking, and the form of that risk-taking, depends on opportunities presented in the adolescent's social context. For example, the leading cause of death for adolescents and young adults is motor vehicle crashes.⁹¹ Alcohol use plays a part in this statistic (see below), but car racing (or just driving fast) is an exciting activity for young males, and one that reward-seeking teenagers are likely to pursue, given the opportunity. But most teens will only engage in this activity when they are licensed to operate a vehicle by the state. Thus, while a 14 year old has reward-seeking inclinations that are similar to those of an older teen, he will seldom engage in reckless driving.⁹² Similarly, most New York City teenagers simply do not have the opportunity to engage in this form of risk-taking.⁹³

The same analysis applies to other forms of risk-taking such as alcohol and drug use. Although under-age drinking is common, acquiring alcohol becomes easier as individuals approach the legal minimum drinking age. College students and other young adults engage in underage drinking at far higher rates than do high school students.⁹⁴ Indeed, one rationale for setting the minimum age for purchasing alcohol at 21 was to reduce illegal drinking among *high*

⁹⁰ ROBERT E. LARZELERE ET AL., *AUTHORITATIVE PARENTING: SYNTHESIZING NURTURANCE AND DISCIPLINE FOR OPTIMAL CHILD DEVELOPMENT* (2013).

⁹¹ Laura Kann et al., *Youth Risk Behavior Surveillance – United States, 2015*, 54 SURVEILLANCE SUMMARIES 1 (2016).

⁹² Of course the younger unlicensed teen may be a passenger in a vehicle driven by an older teen.

⁹³ Also cultural influences may be important. As noted earlier, a recent study of cross-cultural differences in adolescent risk taking found greater variability in real-world risk taking than in laboratory based measures of risk-taking propensity. Duell, et. al., *supra* note 68.

⁹⁴ National Research Council, Committee on Juv. Justice Reform, *Reforming Juvenile Justice: A Developmental Approach* (2013).

school students.⁹⁵ Lawmakers thought that lives would be saved by creating a substantial gap between the age at which individuals have ready access to alcohol and the minimum driving age. But because alcohol is legal for adults (who are presumed less inclined toward risk-taking), it is readily available in every community, and not surprisingly, a relatively high percentage of adolescents experiment with drinking. Also unsurprisingly, given the relatively lower driving age in the United States than in most of the developed world, automobile fatalities among adolescents are higher here than abroad.⁹⁶

Illegal drug use is another risky activity that might well appeal to many normative adolescents--reward-seeking individuals with immature impulse control, who are inclined to focus on short-term benefits and discount long-term costs. But drugs, in contrast to alcohol, generally cannot be acquired legally, and use and sale can result in criminal penalties. Thus access and opportunities to engage in this risky activity are more limited and drug use among adolescents is less prevalent than alcohol use; again, the teenager's social context play a role in the form of risk-taking teenagers choose.

Teenagers' inclination to engage in unsafe sex provides a somewhat different variation on the theme, but also demonstrates how social context can increase or decrease the inclination to engage in risky activities. If teenagers are encouraged to use contraceptives and condoms, and such protection is readily available, the incidence of unsafe sex and pregnancy will be lower than if protection is difficult to obtain.⁹⁷ The immediate decision to have sex is likely to be driven by the reward-seeking, impulsive inclinations of adolescents, who may fail to consider the potential serious long term consequences. But if the adolescent can easily acquire contraceptives, the decision to have safe sex can be made in a more neutral setting in which the adolescent can rationally consider the benefit of avoiding pregnancy and disease.⁹⁸

⁹⁵ FRANKLIN E. ZIMRING, *THE CHANGING LEGAL WORLD OF ADOLESCENCE* (2013).

⁹⁶ Organization for Economic Co-operation and Development (OECD) & International Traffic Safety Data and Analysis Group, *Road Safety Annual Report 2013* (2013).

⁹⁷ Douglas B. Kirby, *The Impact of Abstinence and Comprehensive Sex and STD/HIV Education Programs on Adolescent Sexual Behavior*, 5 *SEXUALITY RESEARCH. & SOC. POL'Y* 18 (2008).

⁹⁸ Experts attribute a decline in teenage pregnancy rates recently to policies designed to facilitate contraceptive use by authorizing minors' independent access to contraceptives in convenient locations. Some evidence suggests that declines in teen pregnancy are linked to the increased use of long-acting reversible contraceptives that mitigate the effects of adolescent impulsivity. See e.g. Justin T. Diedrich et al., *Long-Acting Reversible Contraception in Adolescents: A Systematic Review and Meta-Analysis*, 216 *AM. J. OBSTETRICS & GYNECOLOGY* 364.e1 (2017) at [http://www.ajog.org/article/S0002-9378\(16\)46213-7/fulltext](http://www.ajog.org/article/S0002-9378(16)46213-7/fulltext)

Adolescent involvement in criminal activity receives more attention from policymakers than any other form of teenage risk-taking. We postpone a comprehensive analysis of this issue until we have explored the role of peer influence, the primary dimension of social context influencing teenage criminal choices. But as our analysis in this section suggests, many other variables in the adolescents' social context can increase or decrease the likelihood that teenage risk-taking involves criminal activity, and, if so, the form of criminal activity. We have discussed the role of parents and the availability (or not) of activities that might tempt the reward-seeking teenager. But social context also includes the adolescent's neighborhood, school and community, each of which can either constrain or encourage the adolescent's inclination to get involved in risky, antisocial activities. The school, for example, may be a well-managed facility in which discipline is maintained and students, supervised by authoritative adults, engage in positive learning experiences and extra-curricular activities. Alternatively, the school can be a chaotic setting in which teachers and administrators have little control over students, and those students who are so inclined are free to pursue antisocial activities. In either case, social context plays a key role in deterring or facilitating antisocial activities.

2. Peer Influence and Risky Activity

Peers constitute the environmental stimuli that most powerfully influence adolescents' involvement in risky activities. As Part I showed, adolescents are susceptible to peer influence to a greater extent than either younger children or adults, and also seek peer approval, which may involve initiating activities that peers will find exciting or pleasurable. In addition, recent research has shown that the mere presence of peers activates the brain's reward circuitry to a much greater extent among adolescents than adults, and that this heightened activation is linked to increased risk-taking.⁹⁹ Thus, peers play a major role in creating opportunities for risk-taking and in influencing whether an adolescent pursues particular opportunities otherwise available in the social environment.

The adolescent propensity for risk-taking is normative, but its form and extent are often driven by peers. Indeed, despite the hard-wired developmental traits that facilitate engagement in

⁹⁹ Chein et al., *supra* note 24. As described in Part I, an adolescent in a laboratory setting who is merely told that he or she is being observed by peers experiences heightened activation in brain regions associated with reward processing and tends to take greater risks in completing assigned tasks than one who believes that he or she is alone.

risky behavior, solitary risk-taking is less common among adolescents than among adults.¹⁰⁰ In real world settings, adolescents and young adults typically drink alcohol, use drugs, exceed the speed limit, and (particularly) commit crimes in the presence of, or in complicity with, peers to a greater extent than older adults.¹⁰¹ It is often forgotten that peers can influence teens in both pro-social and anti-social directions.¹⁰² Pro-social peers can reinforce the goals of getting good grades and excelling in socially useful activities.¹⁰³ Indeed, Research demonstrates that peers can have direct positive impact on adolescent risk behavior. For example, one laboratory-based study using a driving simulation game found that adolescents ages 16-17 demonstrated safer driving while in the presence of a cautious (rather than risky) peer, regardless of individual differences in susceptibility to peer pressure.¹⁰⁴ But peers who encourage, facilitate or support involvement in risky activities can serve as catalysts that mobilize the adolescent's proclivity for sensation-seeking and direct it toward potentially harmful actions.

Peer groups vary in the extent to which antisocial risk-taking plays a role in their social interactions. Some teenagers associate with peers who only occasionally engage in dangerous risk-taking, while others are part of antisocial peer groups heavily involved in one or more forms of illicit activities.¹⁰⁵ But no sharp dichotomy typically exists between pro-social and anti-social peers. A broad range of adolescents are attracted to exciting activities that may be associated with physical and social risks. Thus generally pro-social teenagers can sometimes instigate or participate in potentially harmful activities, just as antisocial adolescents also sometimes respond to peer influence to engage in socially desirable behavior.¹⁰⁶

Most adolescents experiment with some mix of the risky behaviors described earlier. But whether a teenager engages in a particular form of risk-taking, and to what extent, is influenced by its availability, and also influenced by the preferences of the peer community, interacting with broader cultural factors that can vary over time and across cultures. For example, teenage drinking and drug use have been more popular in some historic periods than others, and peer sub-communities may vary in their substance of choice. Criminal activity is also influenced by cultural factors. Criminologists credit the widespread availability of guns as a key contributor to the spike in juvenile homicide rates in the late 1980s and early 1990s.¹⁰⁷ Disputes that were settled through fistfights in an earlier era were resolved with guns in the late 20th century.

Only recently has research directly shed light on how the interaction between the individual adolescent and the peer group facilitates participation in risky activities. A study by Jason Chein and colleagues found that the presence of peers leads to increased risk-taking by adolescents but not adults. The study also found that peer presence activated the brain regions associated with the anticipation of potential rewards in adolescents, suggesting that greater neural activation in the brain's reward centers is associated with increased risk taking. Importantly, in this study, subjects were merely *told* that they were being observed by peers from another room; the responses in brain activity and risk-taking were not due to actual peer pressure.¹⁰⁸ Other studies from this team of scientists have shown that, even in the absence of opportunities to engage in risk-taking, the presence of peers activates adolescents' reward centers and increases adolescents' preference for immediate rewards.¹⁰⁹

It is possible to hypothesize with some confidence the dynamic between individual adolescents and peers that leads to risky activities in real-world settings when we consider the following: a) normative adolescents are particularly susceptible to peer influence due to heightened sensitivity in the social brain; b) peers collectively constitute the primary component of social context for the individual adolescent, and c) those peers themselves typically are sensation-seeking adolescents, who are prone to acting impulsively under conditions of

¹⁰⁷ Zimring, *supra* note 96.

emotional arousal, and whose sensitivity to rewards is activated in the peer group context. In combination, it is unsurprising that the interaction among adolescent peers can be volatile, as one or more teenager serves as an active catalyst, encouraging others to participate in risky behavior that none would undertake on his or her own.

This dynamic interaction between individual and peers plays out against a backdrop in which opportunities to engage in risky activities vary, as described above. The patterns of risk-taking varies with age; for example, 15-year-olds drink alcohol less than 20-year-olds. It also varies with parental norms and supervision, neighborhood, school setting and other factors that determine whether, how, and if sensation-seeking adolescents act on their impulses.

It is well established that risk-taking declines as individuals mature. Most forms of risky behavior peak in late adolescence and early adulthood,¹¹⁰ a trend that is observed across cultures that vary in their social, political, cultural, and economic contexts.¹¹¹ This pattern likely reflects the reality that many forms of risky behavior are driven by the interaction of an immature individual and a social context of peers who encourage risk-taking.¹¹² As adolescents mature, their propensity for sensation-seeking declines and the brain's executive functions improve, along with communication between the pre-frontal cortex and emotional centers of the brain. This maturation process results in better emotional regulation and behavioral control in arousing contexts, reducing impulsivity and the inclination to engage in risk-taking, including criminal activity. Importantly, this developmental process toward maturity proceeds in most adolescents, such that the individual's social context changes as his peers also mature; he is no longer surrounded by sensation-seeking peers, inclined, as he was, to make impulsive choices when emotionally aroused.¹¹³

A key insight of this analysis is that the primary exogenous influence on normative adolescent risk-taking is other adolescents, who as individuals are themselves inclined toward risk-taking, and who collectively constitute the main component of the teenager's social context. As individual adolescents mature, they become less susceptible to peer influence, less inclined

¹¹⁰ Steinberg, *supra* note 11.

¹¹³ Sweeten, Piquero & Steinberg., *supra* note 73.

toward sensation-seeking and less impulsive; this maturation process also diminishes the individual's role as part of a risk-promoting peer context. Thus, each adolescent is both an individual maturing into adulthood who is becoming less inclined toward risk taking, and part of the social context that is becoming less facilitative of risk-taking, in part, as discussed below, due to the assumption of work and relationship responsibilities.¹¹⁴

C. Adolescent Criminal Activity and Social Context.

In conversations about crime prevention and public protection, juveniles are usually treated as a sub-category of offenders—a group that offends at high rates due to adolescent immaturity. But most adolescent involvement in criminal activity has more in common with teenage drinking, unsafe sex and car racing than with the criminal choices of adult offenders. For our purposes, it is more useful to view juvenile offending as a form of adolescent risk-taking than as a discrete form of antisocial behavior. It is often observed that age 17-18 is the peak age for involvement in criminal activity, and that the crime rate falls steeply after the early 20s.¹¹⁵ Other risky behavior follows a similar pattern, and developmentalists generally think the same biological and psychological mechanisms underlie criminal activity as other forms of risk-taking.¹¹⁶ Thus, juvenile offending often may be attributed to youths acting upon a developmentally normative drive toward novel, exciting experiences. In the appropriate social context, this drive for sensation and risk is directed toward antisocial or delinquent behaviors.

Like other forms of risk-taking in adolescence, criminal activity involves a dynamic interaction between the still maturing teenager and his or her social context. And as is true with other risk-taking, the impact of social context can deter or facilitate antisocial behavior. Thus, authoritative parents can provide structure and supervision for their children that reduce the risk of youthful offending, while disengaged parents likely perform no such deterrent function. Indeed, research suggests that greater parental monitoring is associated with longitudinal decreases in delinquency and aggression among young adolescents, regardless of affiliations

¹¹⁴ Research indicating low rates of exposure to delinquent peers in early adolescence, increasing rates in middle and late adolescence and declining rates thereafter is consistent with this point. Warr, *Age, Peers and Delinquency*, 31 *Criminology* 17 (1993). Early adolescents as individuals are developmentally less inclined toward antisocial behavior than older teens; thus the peer group of delinquent teens is small.

¹¹⁵ Manuel Eisner, *Crime, Problem Drinking, and Drug Use: Patterns of Problem Behavior in Cross-National Perspective*, 580 *ANNALS AM. ACAD. POL. & SOC. SCI.* 201 (2002); Sweeten, *supra* note __, ND 114 Scott, Bonnie & Steinberg, *supra* note 60.

with delinquent peers.¹¹⁷ Neighborhoods also vary as social contexts for offending. In low-crime neighborhoods, non-criminal residents perform an informal monitoring function that may discourage criminal activity, simply by being out and about on the streets and sidewalks and in the parks.¹¹⁸ In high-crime neighborhoods, in contrast, residents may stay indoors out of fear for their safety, providing greater opportunity for criminal activity.¹¹⁹ Neighborhood conditions may also reinforce both antisocial behaviors and psychological traits such as impulsivity. Community violence has been linked to disrupted behavioral control¹²⁰ and perpetual hyper-arousal among youth.¹²¹ Further, dangerous environments can teach youth that violence is an effective method of problem solving, and therefore violence and delinquency become learned behaviors.¹²² For individuals living in high-crime neighborhoods who feel chronically threatened, carrying a gun and acting reflexively or impulsively are likely adaptive behaviors. As suggested above, schools also can be safe and supervised educational settings, or environments in which adolescents, gathered together in close proximity for extended periods, are subject to few exogenous constraints and many temptations to engage in antisocial behavior. Further, the extent to which youth are engaged in educational pursuits and feel connected to their school is correlated with long-term effects on adolescent delinquency and substance use.¹²³

As we have indicated, peers constitute the element of social context most likely to activate individual adolescents' reward-seeking tendencies, and typically peers are the most important contextual contributor to risk-taking. Research confirms that affiliation with antisocial peers is the factor most predictive of juveniles' involvement in criminal activity.¹²⁴ Even adolescents who are not inherently delinquent or antisocial are more likely to engage in

antisocial behaviors when they socialize in groups of teens in unstructured, unsupervised settings; this finding highlights the important role of context in facilitating adolescent risk behavior.¹²⁵ In this section, we examine how antisocial peer affiliation develops and probe the interaction between the individual and his or her adolescent peer group as that interaction relates to offending. This interaction can shed some light on the functioning of juvenile gangs. It also informs our understanding of the role of peers in the trend toward desistance in early adulthood.

1. Affiliation with Antisocial Peer Groups

Although most adolescents engage in risk-taking, including some forms of criminal activity, most do not associate with peers whose risk-taking takes the form of chronic or serious criminal activity. Why do some adolescents tend to affiliate with antisocial peers while others find friends less likely to get into serious trouble? This question has been the focus of some research in recent years; not surprisingly, it appears that several factors contribute to peer group affiliation.

First, the tendencies and traits of the individual adolescent play a role in peer associations. Some teens are more inclined toward sensation-seeking and are more impulsive than the norm, and may be attracted to the extreme risk-taking activities of antisocial peers; others may lack the social skills to affiliate with more desirable peer groups. Studies of peer group formation show that some teenagers resort to antisocial peer groups because they are rejected from higher-status crowds.¹²⁶ Of course, intense sensation seekers might also associate with peer groups that pursue extreme sports or other dangerous activities, but some will likely be attracted to a peer group that engages in criminal activity if such a group is available or if access to more prosocial groups is constrained.

Parents play an important, if indirect, role in their children's peer group associations. Research has found that parents' values and preferences about their children's associations seems to influence adolescent peer group affiliations.¹²⁷ If parents are distant and fail to monitor their children, or if parents themselves endorse antisocial or criminal norms, it is more likely that

teenagers will affiliate with deviant peer groups.¹²⁸ One study found evidence that parents fostered certain traits or behavior patterns in their children, which then predicted peer group affiliation.¹²⁹ Moreover, parents' influence on peer affiliation likely predates adolescence. Snyder and colleagues found that parental failure to discipline their children's antisocial behavior to be a precursor to association with deviant peers.¹³⁰ Parents also determine the neighborhood, community, and school in which the teen will live, and this in turn will determine the peer groups that are *available* for affiliation. Of course, parents themselves may have few residential options and economic and social constraints that restrict poor families to high-crime neighborhoods can mean that delinquent peers are ubiquitous. In this situation, the adolescent's social context may offer few pro-social peer group options.

This last point is important in understanding why adolescents in some neighborhoods and communities are far more likely to associate with deviant peers than teenagers in other settings. In some neighborhoods, most male peer groups are committed to involvement in criminal activity; the realistic options may not include pro-social peer groups. The choices available to individual teens may also be limited by neighborhood geography; urban teenage gang members typically live in close proximity to one another. The alternative of avoiding peer affiliation altogether is unattractive to most teenagers, although it may appeal to parents seeking to protect their children from gang involvement. Further, in high-crime neighborhoods, peer group affiliation may be deemed a source of security as well as excitement and camaraderie. Hostility among adolescent peer groups may leave the unaffiliated youth vulnerable to attack and harassment. And gang membership provides a defense against attacks by other gangs.¹³¹ The upshot is that adolescents in poor, high-crime neighborhoods may be very limited in their peer group options; many will affiliate with deviant peers, as "the only game in town." and are likely to be influenced by that association to engage in criminal activity.

¹²⁸ Several early studies found a link between affiliation with deviant peers (usually involved in drug use) and parental modeling or disengagement. Denise B. Kandel & Kenneth Andrews, *Processes of Adolescent Socialization by Parents and Peers*, 22 *Int'l J. Addictions* 319 (1987); E.R. Oetting & Fred Beauvais, *Peer Cluster Theory, Socialization Characteristics, and Adolescent Drug Use: A Path Analysis*, 34 *J. Counseling Psychol.* 205 (1987).

2. *Peer Group Influence and Juvenile Offending.*

Adolescents' susceptibility to peer influence and desire to please peers can influence juvenile offending in two ways. First, adolescents offend in groups at substantially higher rates than do adults.¹³² The impact of peers on one another in a group setting likely enhances the salience of potential rewards associated with certain behaviors, leading to emotional arousal and sensation-seeking, which in turn may overwhelm the adolescent's still maturing ability to control impulsive behavior. Thus, the prospect of acquiring money or vanquishing a rival gang that poses a threat becomes more exciting in the peer context. Each youth is also sensitive to the approval of others in the group. As the planning of the crime proceeds, withdrawal by individual youths is likely very costly, as it may lead to rejection and even exclusion from the peer group. Moreover, in his emotionally aroused state, the adolescent is more likely to focus on the potential short-term rewards of the criminal act, and to pay scant attention to the potential downside.

The power of peer influence on the individual adolescent operates even without overt peer pressure or even presence.¹³³ Thus, a second form of peer influence occurs if a teenager acts with the goal of positively impressing his peer group. A juvenile seeking peer approval might act alone to steal something, in excited anticipation of his friends' approving response. This variation is important for two reasons. First, it suggests that anticipated peer response has a powerful influence on adolescents even when peers are not present.¹³⁴ And second, it suggests that identifying an adolescent as a leader (or initiator of criminal activity) or follower may sometimes not be a meaningful distinction. An adolescent who acts to impress antisocial peers may simply be conforming to peer group expectations.

We can only tentatively describe the actual process through which individual adolescents in an antisocial peer group plan and execute a criminal offense; not surprisingly, field research has not been undertaken. But the body of developmental knowledge that we have described can inform our understanding of the interaction between individuals and peer groups in this context. The following scenario comports well with developmental knowledge: Several friends are hanging out on a Friday evening when one suggests robbing the local convenience store. As the

¹³²Zimring & Laqueur, *supra* note 42.

¹³³ Chein, *supra* note 24 (describing study in which subjects were told that peer was watching them perform task; adolescents took more risks than adults).

¹³⁴ Chein, *id.*

group discusses the idea, they become excited at the prospect of the cash they will acquire in the hold-up; several advocate eagerly for the plan and others join in the enthusiasm. Most do not consider the potential risks they may face, including the risk of apprehension or the possibility that the store clerk will be armed and will fire in self-defense. They also do not think about the cost of a delinquency adjudication to their future lives. Those who do consider the potential risks may decide that the benefits of the act (e.g., peer approval, earning money, having fun) outweigh the potential costs. Any youth who has qualms about the plan is silent, not wanting to earn the anger or ridicule of his friends.

In situations of gang rivalry, involvement in criminal activity may implicate more complex responses in adolescent gang members than the reward-seeking impulses associated with juvenile offenses aimed at financial gains.¹³⁵ When juvenile gangs compete with one another for territorial dominance, individual members of each gang is likely emotionally aroused by the prospect of the gains associated with victory over the rival. But a rival gang also poses a threat of physical harm; and adolescents are emotionally aroused by potential threats as well as rewards.¹³⁶ The dual sources of emotional arousal experienced by gang members may escalate the response, creating in individual members of each gang a hyper-vigilance to anticipated attack and urgent desire to preempt the rival in attaining territorial goals. In planning a gang activity, individual members are likely to reinforce one another in their excitement about the prospect of attaining the goal, with little immediate attention to the risk of injury or death inherent in the confrontation. But as the confrontation unfolds, the threat of harm becomes highly salient, triggering quick responses. This dynamic interaction between the individual adolescent and his peer group in a hostile, threatening, context invites impulsive responses that often involve violence.¹³⁷

3. *Social Context and Limits on Exit.*

NEUROSCI. 1565, 1565-82 (2008) (compared to adults ages 21-40, adolescents ages 9-17 evinced greater activation to fearful faces in the amygdala, which is responsible in part for processing emotional information); Jeffrey M. Spielberg, Thomas M. Olino, Erika E. Forbes, & Ronald E. Dahl, *Exciting Fear in Adolescence: Does Pubertal Development Alter Threat Processing?* 8 DEV. COGN. NEUROSCI. 86, 86-95 (2014).

¹³⁷ Katz, et.al., *supra* note 130.

The Supreme Court in its juvenile sentencing opinions has underscored a final point about social context and juvenile offending. A juvenile by virtue of his status as a legal minor cannot escape his family, neighborhood or his limited options for peer associates.¹³⁸ Unlike an adult, who (theoretically, at least) can leave the temptation of a high-crime neighborhood, a juvenile cannot extricate himself.¹³⁹ Thus the adolescent whose circumstances have placed him in a social context that encourages involvement in crime, does not have the option of moving to a community in which he can enjoy the benefit of authoritative parents, an enriched educational setting, a safe neighborhood and pro-social peers, elements of social context that would reduce the likelihood that he will get involved in serious crime.

4. *Social Context and Desistance from Criminal Activity.*

It is well established that criminal offending increases through adolescence, peaks between age 17 and 18 and declines sharply thereafter.¹⁴⁰ This pattern is similar to that observed for other forms of risk-taking, although the peak age varies somewhat for different types of risky behavior.¹⁴¹ It also seems very likely that the factors contributing to the decline in other risk-taking in late adolescence and young adulthood also drive desistance from criminal activity. Most importantly, desistance from crime is correlated with the declining susceptibility to influence from antisocial peers. Substantial evidence supports that the decline in affiliation with antisocial peers as adolescents transition to adulthood is the most important contributor to the declining rate of participation in crime post-adolescence.¹⁴²

Most adolescents desist from offending (and other forms of risk-taking) through a process that is linked to maturation; as the individual adolescent and his peers mature, the dynamic interaction that propelled much juvenile offending weakens. Reward-seeking and extreme sensitivity to peers, developmentally normal tendencies in adolescence, decline with maturity; as the individual ages, he or she is less prone to emotional arousal at the prospect of criminal

¹⁴² Sweeten, Piquero & Steinberg., *supra* note 73.

activity with peers.¹⁴³ At the same time, decision-making improves as the young adult becomes less impulsive and the executive functions of the brain operate more effectively, facilitating the regulation of emotions and consideration of future consequences.¹⁴⁴ As noted earlier, because this maturation is typical of most adolescents, both the individual and his peers (the most important exogenous contributor to adolescent involvement in crime) are changing. The individual becomes less inclined to offend, and the peer group is less likely to play its facilitative role of inducing emotional arousal and promoting criminal activity. The excitement associated with criminal activity declines while the potential costs and risks become more salient.¹⁴⁵

As adolescents mature into adulthood, social context changes in other ways that likely contribute to desistance from offending. Robert Sampson and John Laub have argued that employment and spousal roles in adulthood encourage desistance from involvement in criminal activity.¹⁴⁶ For most adults, these conventional roles provide structure and a social context that limits opportunities for risk-taking. The time demands and routines of work and family responsibilities make participation in criminal activity more costly. This account is compatible with the rationale for desistance that emphasizes the impact of adolescents' normal maturation on both the individual propensity toward offending and the peer group's catalytic role. Maturity is required to function in the conventional adult roles that bring stability to the lives of formerly antisocial youth; sensation-seeking, impulsive adults are unlikely to be successful as employees and life partners. Moreover, as peers themselves mature and assume adult roles, social pressure to engage in criminal activity likely declines and mainstream social norms encourage responsible fulfillment of role obligations.¹⁴⁷

D. Non-Normative Antisocial Behavior in Adolescence

It is well understood that not all offending by juveniles can be explained as a product of the interaction between immature, but developmentally normative, adolescents and their peers, who are themselves immature teenagers. Some individuals are inclined toward serious antisocial

¹⁴³ See discussion, *supra* note _

¹⁴⁴ Note _ and accompanying text.

¹⁴⁷ *Id.* at _.

behavior in childhood; in this, they differ in important ways from teens whose involvement in criminal activity begins in adolescence. Some early-onset offenders may also desist as they mature,¹⁴⁸ but normative brain development in adolescence, by definition, does not contribute to their early maladaptive behavior. Moreover, although most juvenile offending declines sharply beginning in late adolescence, some individuals persist in criminal pursuits into adulthood; either they have failed to mature or maturation has not led them to desist from criminal activities. Although this category of offenders is small compared to normative juveniles, it includes the most serious offenders who cause the most social harm.

Comprehensive examination of early-onset offenders and “life-course-persistent”¹⁴⁹ offenders is beyond the scope of this article. Nonetheless, brief consideration of these individuals (and how their involvement in crime differs from that of normative adolescents) is in order. Developmentalists and criminologists agree that several factors contribute to serious antisocial behavior in childhood, including hyperactivity and attention-deficit disorders, other neurological deficits, learning disabilities and inadequate or abusive parenting. Early-onset offenders are often children with complex problems whose parents are incapable of providing adequate supervision and the support needed to overcome the challenges they face. (Indeed, even adequate parents may be unsuccessful in dealing with these children).¹⁵⁰ Thus, the source of their antisocial behavior may endogenous, or it may be the product of an interaction of individual factors and childhood social context. Unlike normative adolescent offenders, however, the individual factors are not primarily normal developmental influences- and peers do not constitute the primary influence of social context. But when these children persist in their antisocial behavior into adolescence, their individual deficits may combine with normative influences associated with adolescence, making them particularly vulnerable and likely to engage in criminal activity.

Some adolescent delinquents become adult criminals; their offending can no longer be attributed to normal developmental immaturity and the predictable influence of normative peers. This group includes early onset offenders, but also individuals who began to offend in

¹⁴⁹ Terrie E. Moffitt, *Adolescence-Limited and Life-Course-Persistent Antisocial Behavior: A Developmental Taxonomy*, 100 Psychol. Rev. 674 (1993). Moffitt offers a taxonomy in which most juvenile offenders are “adolescence-limited;” their offending begins and ends in adolescence. A small group, however, are “life-course persistent” offenders, whose antisocial conduct begins in childhood and continues into adulthood.

¹⁵⁰ Id. at _.

adolescence.¹⁵¹ In the latter case, as we discuss below, the individual's life trajectory may have been shaped by his interaction with the justice system, and by sanctions that impede normal development. In general, however, the impulsive, sensation-seeking behavior of the adult criminal will be taken to represent individual characterological deficits and not residual adolescent immaturity from which the individual is likely to emerge. For our purposes, the important point is that we currently lack the tools to distinguish accurately during adolescence the normative juvenile offender who likely will mature out of his or her tendency to get involved in crime from emerging career criminal or the psychopath.¹⁵² Because the vast majority of adolescents who violate the law do not become chronic adult criminals, information about an offender's adolescent misbehavior is seldom predictive of adult criminality.

III. Correctional Programs as Social Settings

To this point, we have focused on how the dynamic interaction between the still-maturing teenager and his or her peers (and other environmental influences) contributes to risk-taking, including criminal activity. But the extreme sensitivity of adolescents to their social context has a broader impact on their development to adulthood; the individual's interaction with her social context during adolescence can determine whether he or she accomplishes developmental tasks essential to successful maturation. For adolescents in the justice system, correctional facilities and programs constitute their social context and can have a critical impact on whether they successfully navigate the transition to productive adulthood.

Developmental psychologists explain that adolescence is a formative period of psychological and social development, during which an individual's experience can shape the trajectory of his or her future life. During adolescence, individuals begin to acquire skills and capacities necessary for successful maturation and the assumption of conventional adult roles of

employee, spouse (or intimate partner) and citizen.¹⁵³ For most adolescents, this maturation process depends on several conditions in the social context that provide “opportunity structures”¹⁵⁴ for healthy development. Two of these conditions represent the obverse of the elements of social context that promote antisocial risk-taking: The presence of an authoritative adult who cares about the youth and can provide guidance and structure,¹⁵⁵ and membership in a pro-social peer group (and minimal influence of antisocial peers). A third important condition of a healthy social context is more indirectly implicated in risk-taking: Participation in meaningful activities that promote autonomous decision-making and critical thinking. The accomplishment of essential developmental tasks in adolescence typically involves reciprocal interaction between the individual and a social context that provides these conditions.

In recent years, this view of adolescence as a formative period in psychological development has been buttressed by work in developmental neuroscience indicating that adolescence is a heightened period of neural plasticity.¹⁵⁶ “Plasticity” refers to the capacity of the brain to change with experience. Neuroscientists distinguish between two types of plasticity; “developmental plasticity” permits large-scale transformations in brain circuitry, including the development of new circuits and the disappearance of old, unnecessary ones, while “adult plasticity” only allows for minor modifications of existing brain circuits.¹⁵⁷ Adolescence is thought to be the last period of developmental plasticity.

Adolescence is a unique period of developmental plasticity in four important respects, all of which have implications for juvenile justice policy and practice:

¹⁵⁷ The brain is always somewhat plastic—it would be impossible to learn new skills or acquire new information if it were not. Charles A. Nelson III & Margaret A. Sheridan, *Lessons from Neuroscience Research for Understanding Causal Links Between Family and Neighborhood Characteristics and Educational Outcomes*, *in WHITHER OPPORTUNITY?: RISING INEQUALITY, SCHOOLS, AND CHILDREN’S LIFE CHANCES* 27-46 (Greg J. Duncan & Richard J. Murnane ed., 2011).

First, adolescence is a second period of particularly heightened plasticity, the first being the first few years of life. It has long been known that the brain is particularly sensitive to the environment during the early years, an observation that has understandably motivated much discussion about the importance of investing in high-quality prenatal and postnatal care, child care, and early education. But more recent research has revealed that the brain undergoes a second burst of plasticity at adolescence. The underlying mechanisms of this burst in plasticity have only recently begun to be articulated, but several studies point to the impact of pubertal hormones on the brain as its likely trigger.¹⁵⁸ We have explained that adolescence is a time during which individuals are especially sensitive to the social environment. But puberty also makes the adolescent brain more *responsive* to environmental input. An important implication of this discovery is that the social context in which the adolescent spends time may have a more profound impact on his or her behavior than during childhood or adulthood. Not surprisingly, this knowledge has begun to inform discussions about the treatment of young people in the justice system.

Second, the brain regions that are thought to be especially plastic during adolescence are those involving the juvenile's response to reward and those involving the development of self-regulation.¹⁵⁹ Because, as we have explained, the interplay between these brain regions is thought to play a crucial role in adolescent risk taking, experiences during adolescence have the potential to enhance or diminish normative development in the very parts of the brain implicated in criminal and other antisocial behavior. That is, experiences during this period have the potential to strengthen or weaken self-control, and to strengthen or weaken reward sensitivity.

Third, the heightened malleability of the adolescent brain is a dual-edged sword.¹⁶⁰ On the positive side, the susceptibility of the adolescent brain to positive influence makes the period one of great opportunity, during which individuals may be especially good candidates for rehabilitative interventions. On the negative side, however, the same plasticity that makes the

brain susceptible to positive influence makes it vulnerable to toxic experiences. Thus, research has shown that adolescence is a time when individuals are particularly vulnerable to addiction, especially responsive to stress, and more likely than at any other time to experience serious mental health problems.¹⁶¹ One important implication of this is that residential and correctional facilities in which adolescents are placed are likely to have a profound impact on juveniles' psychological functioning and development. Harmful correctional experiences, such as exposure to violence or social isolation, are likely to be particularly damaging at this stage of life.

Finally, just as there is a significant increase in plasticity early in adolescence, there is a corresponding decrease during the transition from adolescence to adulthood. The fact that the brain becomes less plastic as individuals mature out of adolescence is now well-established although the mechanisms that trigger this loss of plasticity have yet to be identified. Nonetheless, it is likely that adolescence represents an especially formative period in brain development, and that major changes in the brain become increasingly intractable with age. This creates special urgency to intervene during this period to promote positive psychological functioning.

This research underscores the important impact of juvenile correctional programs on individual development during a critical developmental stage. Thinking about correctional settings as social contexts for development during a period in which individuals are highly sensitive and responsive to that context provides a critical perspective from which to evaluate justice system facilities and programs. As we saw in Part II, negative conditions (or the absence of positive conditions) in the adolescent's social context can contribute to harmful risk-taking. Neglectful parents, antisocial peers, and schools and neighborhoods devoid of productive, engaging activities contribute to juveniles' involvement in crime. Some correctional settings are also likely to have a very negative impact. The social-context framework clarifies why prisons are widely viewed as toxic developmental settings.¹⁶² The likelihood that the juvenile inmate will establish a relationship with an authoritative adult is negligible. Relationships between

Zimring, eds., 2000).

guards and prisoners typically are hostile and distant, and adult inmates are unlikely to care for and provide positive adult guidance to juvenile prisoners.¹⁶³ The juvenile inmate is surrounded by antisocial peers and adults, and often has a great deal of unstructured time in their company.¹⁶⁴ Educational and vocational programs in prison often are deficient and few are tailored to the needs of adolescents. Not surprisingly, juveniles sentenced to prison have high recidivism rates.

This analysis clarifies that even though much juvenile offending is the product of the interaction of immature adolescents and a social context that promotes risk-taking, maturation and desistance are not inevitable. Given heightened brain plasticity during adolescence, social context plays a key role in whether juveniles successfully accomplish the developmental tasks necessary to make the transition to productive adulthood, and it can undermine as well as facilitate progress. Thus the correctional setting in which the juvenile is sanctioned can play an important role in determining the trajectory of the adolescent offender's future life.¹⁶⁵ Programs that aim to facilitate desistance in juvenile offenders and encourage their transition to productive adulthood will attend to the impact of the developing offender's social context and seek to provide the conditions for healthy development.

IV. Legal Implications of the Interactive Framework.

In this Part we explore the importance of the interactive framework that we have developed in this article for legal doctrine and policy aimed at sanctioning juveniles for their crimes and deterring juvenile crime. First, the framework powerfully reinforces constitutional principles under which juvenile offenders generally are deemed less culpable than adults, and more likely to desist from offending as they mature into adulthood. These principles, in turn, support a broad range of justice policies premised on juveniles' reduced culpability and greater potential for reform. Our analysis of the interaction between the individual youth and his or her social context provides an effective response to the skeptics who reject the importance of

¹⁶³ Juvenile prisoners are vulnerable to violent exploitation by older prisoners; alternatively, young inmates may be trained to become career criminals. ¹⁶⁵ See Thornberry, supra note 134, analyzing the impact of gang membership on the trajectory of a young gang member's life.

immaturity as a mitigating factor in criminal liability on the ground that many adolescents do not engage in criminal conduct. Second, our interactive framework clarifies the importance of social context as a legitimate, but limited, contributor to a theory of mitigation, and as such it offers a useful intervention in a longstanding debate among criminal law scholars.¹⁶⁶ Social context, we have shown, has a far narrower, but more direct, impact on adolescents' criminal choices than was recognized by advocates arguing generally that a defendant's "severe environmental deprivation rotten social background" (SED) reduces culpability.¹⁶⁷ Finally, we highlight the policy importance of social context in developing sanctions for juveniles that are likely to promote, and not undermine, healthy maturation and desistance from crime. In general, focusing on the interaction between adolescents and their social context provides a more complete account of juvenile offending and desistance than a model that emphasizes only the immaturity of teenage brains.

A. *Reduced Culpability and Potential for Reform*

The Supreme Court in its juvenile sentencing opinions announced that "Children are different," and cited studies of brain development in concluding that harsh criminal sentences that might be appropriate for some adult offenders are unconstitutional for juveniles under the 8th Amendment.¹⁶⁸ The Court focused primarily on how the immaturity of adolescents can lead them to make impulsive, reckless decisions and engage in "heedless risk-taking;"¹⁶⁹ it also observed that, because their crimes are the product of immaturity, most juvenile offenders will reform as they mature into adulthood and should be given the opportunity to do so.¹⁷⁰ Culpability skeptics have challenged this analysis, pointing to the very serious crimes committed by the juvenile petitioners in the cases before the Court, and observing that few adolescents commit similar crimes.¹⁷¹

It is not our purpose to analyze whether Chris Simmons (who killed a neighbor, bound her, and threw her in a nearby river) was driven by factors associated with adolescent immaturity

or by largely endogenous influences.¹⁷² Instead, we propose that our interactive framework provides important confirmation of the Supreme Court’s “children are different” principle and shows that the skeptics’ critique targets a narrow and empirically incomplete version of the Court’s mitigation analysis. Indeed, the Court in its sentencing opinions underscored the importance of social context and adolescents’ normative sensitivity to that context as a key feature of juvenile offenders’ reduced culpability. In *Miller*, the Court stated that juveniles are “constitutionally different from adults for purposes of sentencing, in part because they are more vulnerable . . . to negative influences and outside pressures, including from their family and peers;” they have “limited control over their own environment,” and “lack the ability to extricate themselves from horrific crime-producing settings.”¹⁷³ In these words, the Court succinctly summarized its understanding that important dimensions of the reduced culpability of juveniles and of their potential for reform are both their extreme sensitivity to social context (an endogenous developmental factor), and that social context itself (an exogenous influence). Neither of these contributors to juvenile offending is substantially within the control of the juvenile.

This point deserves elaboration. Adolescents’ sensitivity to social context, and particularly to emotional arousal in the presence of peers, is endogenous, associated with development of the social brain after puberty. The adolescent’s control over this aspect of development is no greater than her control over other aspects of brain development, including the inclination toward reward seeking or the tendency to make impulsive choices when aroused. To the extent that normative developmental immaturity mitigates juveniles’ criminal culpability, susceptibility to peer influence and sensitivity to social context are as salient as other endogenous influences on decision-making. Further, like the teenager’s inclination toward reward-seeking, susceptibility to peer influence declines with maturation. It is one dimension of developmental change that support the Supreme Court’s conclusion that juvenile offenders have a greater potential for reform than their adult counterparts. In short, the endogenous features of brain development that make adolescents particularly sensitive to social context function as do other

¹⁷² Chris Simmons was the petitioner in *Roper v. Simmons*. The Supreme Court finding his death sentence unconstitutional did not focus on Simmons individually, but observed the difficulty in distinguishing between the juvenile who was “irretrievably depraved,” *Roper*, 545 U.S. at 553 from the adolescent whose crime represented transient immaturity.

¹⁷³ *Miller v. Alabama*, 132 2455 – (quoting in part *Roper v. Simmons*, 543 U.S. 551, _ (2005)).

aspects of social-emotional brain development to distinguish juvenile offenders from adults. In combination, these features play a key role in criminal choices and support greater leniency toward juvenile offenders.

The Supreme Court also recognizes that juveniles often have little control over their social context and usually no ability to extricate themselves from a setting that facilitates criminal activity.¹⁷⁴ Children and adolescents do not choose their parents, neighborhoods, schools and communities. Parents may be neglectful and provide little supervision; the neighborhood and school may be dangerous, with little positive structure and few prosocial activities; and available peers may be inclined toward antisocial behavior. These conditions, as Part II explained, create a social context that facilitates youthful involvement in criminal activity. But, as legal minors, teenagers living with these conditions are not free to move to a new neighborhood, enter a new school, or (usually) find prosocial peers with whom to associate. The upshot is that most youths have little ability to control or change a social context that may contribute to their offending. The Supreme Court, in finding social context itself to contribute to juveniles' reduced culpability, in effect recognizes its importance in facilitating teenage criminal behavior.

As skeptics of mitigation based on immaturity observe, endogenous developmental factors alone provide an inadequate basis for treating young offenders as a special category, because many adolescents do not commit serious crimes. Some critics of the recent science-based trend see juveniles as indistinguishable from adults when it comes to criminal liability,¹⁷⁵ apparently viewing antisocial behavior generally as motivated by the individual's deficient character. The Supreme Court, however, recognized that juveniles deserve more lenient treatment than adults, not only because of developmental traits and tendencies, but also because their social context, over which they have little control, impels them to offend. The interactive framework that we have offered strongly supports and elucidates the Court's position.

¹⁷⁴ *Roper*, 543 U.S. at 553. This point is based on the analysis of two of the authors. Scott & Steinberg, *Less Guilty by Reason of Adolescence*, *supra* note 16.

¹⁷⁵ Mark R. Fondacaro, *Rethinking the Scientific and Legal Implications of Developmental Differences in Juvenile Justice Research*, 17 *NEW CRIM. L. REV.* 404 (2014); Yaffe, *supra* note 3.

The Supreme Court’s analysis draws on two conventional sources of mitigation under criminal law doctrine.¹⁷⁶ Mitigation applies to criminal acts that reflect diminished decision-making capacity; like mental illness or intellectual disability, immaturity can be the source of deficiencies in decision-making. As we have explained, social and emotional factors associated with adolescent brain development can undermine teenagers’ capacity for rational decision-making under some conditions. Mitigation also applies to acts that respond to exogenous coercive pressures; indeed, the defense of duress is based on the intuition that a defendant who offends under truly extraordinary pressure is not culpable at all. As our interactive model demonstrates, these sources of mitigation are uniquely interwoven in adolescent criminal choices. Normative endogenous vulnerabilities make teenagers particularly susceptible to exogenous pressures from which they may be unable to escape, leading to impulsive, short-sighted choices.

Our interactive framework also provides strong support for the Court’s conclusion that adolescents should receive less punishment than adult counterparts due to their potential for reform. The biologically-based tendencies that contribute to juvenile offending change and diminish as adolescents mature into adulthood, reducing their inclination to engage in reward-seeking and make impulsive choices in response to social context. At the same time, key elements of the social context also change, as peers themselves mature and become less inclined to encourage risky peer group behavior. Unless the trajectory of normal development is derailed, individuals predictably will make the transition to non-criminal adulthood as they mature.

The developmental framework elucidated by the court in the juvenile sentencing opinions dealt only with the most severe criminal sanctions and affected a small category of young offenders. But, as courts, legislatures and policymakers have recognized, the “children are different” principle applies broadly to the justice system’s treatment of young offenders. Courts have cited *Miller* and other Supreme Court opinions in decisions that have prohibited the use of sentences imposed on juveniles under adult enhanced sentencing schemes,¹⁷⁷ and have excluded juvenile sex offenders from sex offender registries.¹⁷⁸ A few courts have prohibited the use of

any mandatory minimum sentence for a juvenile.¹⁷⁹ Legislatures also have adopted the court’s developmental principles in creating special parole regulations for juvenile offenders.¹⁸⁰ In recent years, states regulators as well have embraced developmental principles in responding to juvenile crime, implementing policies that recognize the unique attributes of young offenders and aim to shape their development to adulthood in a positive direction.¹⁸¹ The upshot is that our interactive framework, in clarifying the interaction between the developing adolescent brain and social context, reinforces the developmental approach to juvenile crime that has emerged in the past decade.

B. “Severe Environmental Deprivation” Revisited

In the 1970s and 1980s, criminal law scholars and judges debated whether a defendant’s impoverished background served to mitigate criminal responsibility.¹⁸² Some scholars argued that offenders who have experienced severe socio-economic deprivation are less culpable than other offenders and deserve less (or no) punishment, because deprivation excuses or mitigates criminal responsibility. Other scholars have argued against this position, on the ground that an offender’s impoverished background is simply not the kind of condition that reduces liability under conventional criminal law principles.

Richard Delgado, the leading proponent of the severe environmental deprivation (SED) defense, points to the reality that a large percentage of offenders come from deprived social backgrounds. On the basis of this correlation, he posits that poverty causes some individuals to commit crimes.¹⁸³ On Delgado’s view, SED can constrain the criminal actor’s free choice as effectively as conventional sources of exculpation and therefore can be accommodated within criminal law doctrine. Delgado describes aspects of living in poverty that contribute to stress and anger in individuals; these environmental influences include inadequate schools, unemployment, substandard housing and other living conditions and a social context that contributes to an “alternative value system.”¹⁸⁴ He argues that these factors in combination could seriously

¹⁸⁴ Id. at 30

undermine behavioral controls, leading the individual to engage in criminal conduct. On Delgado's view, the inclination to commit crime is a pathology caused by poverty.¹⁸⁵

Other scholars have rejected the argument that economic deprivation is relevant to excuse or mitigation for criminal conduct.¹⁸⁶ Stephen Morse has pointed out that causation is a capacious concept and that behavior, including criminal acts, can be traced to many causal factors. On Morse's view, even if poverty contributes to offending in a causal sense, that alone is insufficient to diminish an offender's criminal liability because deprivation does not impede the individual's capacity for rational reflection in making choices in a way that affects criminal responsibility. Nor does the experience of living in poverty create an irresistible compulsion to offend, or make the actor facing a "hard choice" (perhaps made harder by conditions of deprivation) unable to choose *not* to engage in criminal conduct.¹⁸⁷ Thus, offenders who have experienced economic deprivation simply cannot legitimately claim a defense based on conventional exculpatory principles of criminal law.

While SED has interested scholars and advocates, and is sometimes described in passing in treatises,¹⁸⁸ it has had little impact on the law.¹⁸⁹ As Delgado acknowledged in 2011, no state has adopted a defense of extreme economic deprivation.¹⁹⁰ This is not surprising, perhaps. For both conceptual and practical reasons, SED is a hard sell. Courts may fear that applying and limiting the defense would be extraordinarily difficult, if not impossible. With its broad conception of causation and capacious view of mitigating constraints on free choice, the SED defense would transform criminal litigation. A large percentage of defendants could plausibly claim that their crimes were mitigated or excused by the deprivation they experienced. Thus on purely pragmatic grounds, lawmakers have been unwilling to open a Pandora's box by adopting a defense that would also undermine the basic principles of criminal responsibility.¹⁹¹

¹⁸⁵ As Delgado explains, "The kind of pent-up rage and despair that can result from living in a crowded, violent neighborhood can cause an explosion of violence just as disordered brain circuitry can." *Id.* at 76.

¹⁸⁷ Morse, *id.* at _.

¹⁸⁸ See, e.g., Joshua Dressler, *Cases and Materials on Criminal Law* 725-28 (4th ed. 2007).

¹⁸⁹ According to Morse, no legislature and few courts have even considered the defense. Morse, *Severe Environmental Deprivation: A Tragedy Not a Defence*, supra note 18 at 170.

¹⁹⁰ Delgado, *The Wretched of the Earth*, supra note 17 at 5.

¹⁹¹ See Andrew E. Taslitz, *The Rule of Criminal Law: Why Courts and Legislatures Ignore Richard Delgado's Rotten Social Background*, 2 Ala. C.R. & C.L. L. Rev. 79, 121 (2011) ("[The RSB defense violates] basic precepts

The argument for a defense based on severe economic deprivation is far more capacious than our claim that social context interacts with endogenous features of adolescence in ways that can the decision making of young offenders. The interactive framework we describe focuses on the peculiar vulnerability to environmental stimuli of individuals during a discreet stage that is part of normal development; moreover the environmental stimuli that impact criminal choices in our framework are limited to those that influence adolescents *because* of endogenous vulnerabilities associated with this stage. Thus the developmental framework is self-limiting. In contrast, the harm of severe economic deprivation, on Delgado’s view, may begin in childhood and adolescence, but its impact and relevance to criminal responsibility can extend to any adult criminal who has suffered the effects of deprivation. Moreover, the sources of the harm that can impact individual criminal behavior include many aspects of life in an impoverished community, from deficient parenting to physical conditions such as substandard housing to unemployment. Further, Delgado views the inclination to offend as a pathology caused by poverty, not as a response characteristic of a normative developmental stage.¹⁹²

The importance of social context under our framework is specific and limited. Peers and other aspects of the adolescent’s social environment stimulate normal biological tendencies toward reward seeking and impulsivity in ways that undermine the youth’s capacity for rational choice and deliberation. These developmental influences do not excuse the youth from criminal responsibility; the interaction does not deprive the youth altogether of the capacity for rational reflection or result in irresistible compulsion. But a normative adolescent capable of making a rational decision under neutral conditions predictably will act impulsively and with little consideration of future consequences when associating with risk-inclined peers. Also predictably, most youths will outgrow this tendency to engage in risky activity. As the Supreme Court clarified, adolescent immaturity is relevant to the law’s response to juvenile crime for two reasons: First, teenage decision making is impaired due to developmentally-linked influences

of mens rea, entity liability, moral culpability, and duty toward others that violate our whole sense of what defines American criminal law.”); Mythri A. Jayaraman, Rotten Social Background Revisited, 14 CAP. DEF. J. 327, 343 (2002) (“Using Rotten Social Background as an excuse defense is impracticable, because it is nearly impossible to show that, based on his Rotten Social Background, the defendant did not know the nature and quality of his act.”). Morse acknowledges this although his objections are based on the incompatibility of SED with principles of criminal responsibility. *Deprivation and Dessert*, supra note 18 at Morse acknowledges this although his objections are based on the incompatibility of SED with principles of criminal responsibility. *Deprivation and Dessert*, supra note 18 at _.

¹⁹² See note 184 supra.

and, second, most juvenile offenders will mature out of their antisocial inclinations; their welfare, as well as social welfare, will be enhanced if the legal response to their offending offers the opportunity to do so.

To be sure, many adolescents who get involved in criminal activity live under conditions of socio-economic deprivation. But only those aspects of the social context that interact directly with the developing brains of adolescents are relevant to our analysis and only to the extent that these factors contribute directly to normative risk-taking by encouraging reward-seeking and impulsivity. Thus, physical conditions and many environmental influences that likely influence the life trajectories of youth living in poverty are excluded from our analysis, although they may indeed contribute to criminal behavior. This is not to say that lawmakers should ignore the impact of economic deprivation,¹⁹³ but only to clarify that the argument for criminal mitigation on this ground is far broader than the one we are making.

C. Correctional Policy in an Interactive Framework.

Part III explained that correctional programs constitute social contexts for young offenders and that their interactions with correctional settings can shape the trajectories of their future lives. Criminal sanctions that fail to offer conditions important for the accomplishment of essential developmental tasks can undermine the adolescent's maturation to productive adulthood. But correctional programs that embrace the developmental lessons that we have described can maximize the likelihood that the juvenile offender will mature out of his inclination to get involved in criminal activity. Correctional settings that incorporate developmental knowledge help the juvenile to make a successful transition to adulthood by assisting him to acquire the skills and tools needed to assume the adult work and family roles.

Successful correctional programs and facilities will recognize the importance of social context to healthy adolescent development.¹⁹⁴ Effective interventions aim to provide an antidote to the environmental influences that encouraged antisocial behavior by incorporating into correctional programs the three conditions needed to facilitate social development.¹⁹⁵ As Part III

¹⁹³ Clearly amelioration of poverty is good social policy on many grounds including the likely contribution to crime reduction.

¹⁹⁴ See Scott & Steinberg, Rethinking Juvenile Justice, *supra* note 139, at 59.

¹⁹⁵ See Scott & Steinberg, *id.* at 56-58; National Research Council, REFORMING JUVENILE JUSTICE: A DEVELOPMENTAL APPROACH 120 (2013).

explained, these included an authoritative parent or other adult invested in the youth's welfare to provide support and guidance,¹⁹⁶ association with pro-social peers (and limited exposure to antisocial peers),¹⁹⁷ and meaningful activities to assist the adolescent to acquire skills needed for adult roles and to develop autonomy.¹⁹⁸ We each dimension in turn:

First, policies grounded in the interactive framework aim to foster the relationship between the young offender and one or more authoritative adults. Ideally, this can be accomplished by assisting parents to adequately fulfill their role. The most successful community-based correctional programs aim, as a core goal, to enable parents of young offenders to function more competently in their role.¹⁹⁹ These programs teach parents the importance of engagement, supervision and guidance of adolescents as keys to effective parenting and seek to give them the tools to function as authoritative parents. The importance of involving parents in juvenile correctional programs and teaching them to fulfill their critically important role in their children's lives has led experts to insist that residential correctional facilities be close enough to the juvenile's home that parents can participate in rehabilitation programs.²⁰⁰ If parents are unable or unwilling to participate meaningfully in a program aimed at developing their competency, or if their child cannot accept them, another caring adult can serve as a substitute, providing guidance and mentorship.²⁰¹ This adult may be a correctional professional or therapist, or it may be a teacher, coach or social worker with whom the juvenile has, or can develop, a close relationship.

Second, a healthy correctional setting limits the influence of antisocial peers and facilitates engagement with pro-social peers. This presents a challenge in residential programs for juvenile offenders since, by definition, the peer group consists of youths who have

demonstrated an inclination to engage in antisocial behavior. One implication of the developmental analysis is that residential programs should be small and create a structured environment. The residential delinquency programs thought to be most effective follow some version of what has been called the Missouri model, which is based on small facilities near juvenile offenders' homes (to facilitate parental involvement); the program provides structure and adult supervision and limits casual peer contact. For juveniles in community correctional programs, the antisocial peer group represents a serious temptation to return to involvement in criminal activity. Programs that effectively reduce recidivism aim to provide tools that will assist the youth in resisting antisocial peer influence and to facilitate connection with prosocial peers.²⁰² Because integration (or reintegration) of the juvenile offender into prosocial peer groups is so important, a school district policy that segregates or excludes former offenders is problematic as it will likely isolate youths from prosocial influences.²⁰³ Community programs that encourage offenders' involvement in sports and other mainstream peer activities potentially can deter association with antisocial peers and promote healthy peer relationships.

Finally programs that assist young offenders to develop social, educational and vocational skills and to learn to make decisions independently and engage in critical thinking prepare them for adult lives. Youths in the community can participate in mainstream educational programs and programs that assist them to prepare for work roles, under the supervision of correctional professionals who can provide support, encourage compliance with requirements and insist on completion.²⁰⁴ Providing meaningful programming is more difficult in a residential setting, but some states have adopted educational and skill building programs in residential facilities that aim to prepare juvenile offenders for adult life.

Our analysis of the importance of the correctional setting in achieving the law's goal of minimizing recidivism and facilitating healthy maturation has an important general policy implication. Large institutions historically have dominated the juvenile correctional systems in many states; our analysis indicates that these facilities are impoverished social contexts that lack

the conditions that promote healthy development.²⁰⁵ Typically these institutions are in rural settings far from young offenders' (urban) homes, and thus do not readily accommodate involvement of parents in delinquency programs. Staff in large institutions necessarily act as custodians and guards; the setting does not lend itself to the kind of relationship between authoritative adult and adolescent that meets developmental needs.²⁰⁶ Beyond this, juvenile institutions house large numbers of offenders and generally lack the capacity to supervise the residents, exacerbating the influence of antisocial peers on one another. Moreover, rival factions that threaten one another are more likely to develop in an impersonal setting in which teenagers do not know all of the other residents. And finally, large institutions seldom provide the customized educational and skill-building programs needed to prepare juveniles for adult life.²⁰⁷ It is not surprising that as part of the recent reform movement in juvenile justice, many states have closed large institutions and shifted resources to community-based programs.²⁰⁸ An important report by the National Academy of Science strongly recommends closing juvenile correctional institutions. The report explains that if residential placement is needed for the safety of the community or the juvenile, small facilities near the offenders' homes are likely to provide far better developmental settings.²⁰⁹

In general, reformers have favored community-based correctional programs, although few have focused explicitly on how these programs can provide a social context for healthy development more effectively than a residential program.²¹⁰ The view that community programs are superior to residential facilities may seem counterintuitive, in that the social context of the juvenile's peers, family and neighborhood likely contributed to his criminal activity. But a community-based correctional program can assist the juvenile to navigate these social contexts and prepare for adult life in the community by focusing directly on the conditions for healthy development. This kind of program can involve parents in the juvenile's treatment more readily than a residential placement. Programs can also facilitate association with prosocial peers and

engage the juvenile to participate in meaningful activities that prepare him for adult life. The premise of Multi-systemic Therapy, among the most successful correctional programs in reducing recidivism in juveniles, is that the therapist engages with the juvenile in all of the youth's social contexts--family, peers, school and neighborhood.²¹¹ This program assists parents to function more capably and provides juveniles with the tools to avoid antisocial peers and to affiliate with pro-social peers.²¹² To be sure, community-based programs face the challenge of assisting delinquent youths to avoid the temptation of rejoining their antisocial peer groups. But this temptation will exist when the juvenile is released from residential placement, and community-based programs confront the challenge head-on.

Conclusion

Contemporary lawmakers increasingly have recognized the critical importance of adolescent brain development in formulating policies that respond to juvenile crime. Attention has focused primarily on how endogenous biological and psychological factors undermine teenage decision making and contribute to involvement in criminal activity. This article broadens the lens to provide a more comprehensive picture, examining the interaction between the immature adolescent and his or her social context. Our interactive framework clarifies that youthful offending, like adolescent risk-taking generally, is a product of a dynamic relationship between the teenager and her environment. Our analysis of the unique salience of social context during this developmental period provides more robust supports for arguments for mitigation than claims based narrowly on biological and psychological immaturity. It also provides powerful evidence that correctional programs providing young offenders with healthy developmental contexts are more likely to realize the law's goal of crime reduction than sanctions that ignore the importance of social environment.
